

Django Template Filters

Step-by-Step Technical Notes & Syntax Guide (Hinglish)

Overview: Is guide mein hum Django templates ke andar filters ka practical use-cases aur syntax dekhenge. Filters ko hamesha pipe symbol (|) ke through template variables par apply kiya jata hai, jisse render hone se pehle data format ho sake.

1. Text Filters

Yeh filters text aur strings ko format karne ke kaam aate hain. Niche diye gaye table mein commonly used text filters ka syntax aur description hai:

Filter	Description (Hinglish)	Syntax Example
Upper Case upper	Text ko capital letters (uppercase) mein convert karta hai.	<code>{{ post.title upper }}</code>
Lower Case lower	Text ko small letters (lowercase) mein convert karta hai.	<code>{{ post.title lower }}</code>
Capitalize First capfirst	Sirf string ke pehle character ko capital karta hai.	<code>{{ post.title capfirst }}</code>
Title Case title	Har word ke pehle letter ko capital kar deta hai.	<code>{{ post.title title }}</code>
Truncate Chars truncatechars	Ek specific character limit ke baad text ko cut karke ... laga deta hai. (e.g. Starting ke 20 chars).	<code>{{ post.desc truncatechars:20 }}</code>
Truncate Words truncatewords	Word count ke hisaab se text ko cut karta hai, na ki characters ke hisaab se.	<code>{{ post.desc truncatewords:2 }}</code>
Line Break linebreaks	Plain text ke line breaks ko HTML <code><p></code> aur <code>
</code> tags mein convert karta hai.	<code>{{ post.content linebreaks }}</code>

2. Number Filters

Mathematical operations perform karne aur numbers check karne ke liye hum in filters ka use karte hain.

Addition (`add`): Original number mein ek specific value add karta hai.

Syntax: `{{ post.price|add:5 }}` (Agar original price 100 tha, toh output 105 hoga).

Divisible By (`divisibleby`): Yeh check karta hai ki number kisi particular digit se divide ho raha hai ya nahi. Isko `if/else` logic ke saath use karte hain, jaise Even/Odd nikalna.

```
{% if post.number|divisibleby:2 %} <p>Number is Even</p> {% else %}
<p>Number is Odd</p> {% endif %}
```

3. List Filters

Arrays, tags, ya list data ko manipulate karne ke liye Django list filters provide karta hai.

Filter	Description	Syntax Example
First Item <code>first</code>	List ya array ka sabse pehla element nikalne ke liye.	<code>{{ post.tags first }}</code>
Last Item <code>last</code>	List ya array ka aakhiri element nikalne ke liye.	<code>{{ post.tags last }}</code>
Length <code>length</code>	List mein total kitne items hain, unka count/size nikalta hai.	<code>{{ post.tags length }}</code>
Slice <code>slice</code>	List ka ek specific part extract karne ke liye (same as Python list slicing).	<code>{{ post.tags slice:" :2" }}</code>
Join <code>join</code>	List ke items ko kisi specific character (comma ya space) ke through jodne ke liye.	<code>{{ post.tags join:", " }}</code>

4. Conditional & Pluralize Filters

Text ko dynamic counts ya boolean logic ke basis par adjust karne ke liye.

Yes / No (`yesno`): Database ki Boolean values (True, False, None) ko custom strings like "Yes", "No", ya "Maybe" mein map karta hai.

Syntax: `{{ post.author_available|yesno:"Yes,No,Maybe" }}`

Pluralize (`pluralize`): Yeh automatically kisi word ke aage 's' laga deta hai agar uska count 1 se zyada ho.

Syntax: `{{ comment_count }} Comment{{ comment_count|pluralize }}`

Dry Run: Agar value 1 hai toh "1 Comment". Agar value 5 hai toh "5 Comments".

5. Date, Time & Encoding Filters

Dates ko human-readable format mein dikhane aur strings ko web-safe banane ke liye.

Filter Type	Description	Syntax Example
Date Formatting <code>date</code>	Date object ko apne custom string format mein render karne ke liye. (e.g., d M Y = 25 Jan 2024).	<code>{{ post.created_at date:"d M Y" }}</code>
Time Formatting <code>time</code>	Date-time object se sirf time nikalne aur format karne ke liye. (e.g., H:i = 14:30).	<code>{{ post.created_at time:"H:i" }}</code>
URL Encode <code>urlencode</code>	URL strings ko properly encode karne ke liye (spaces aur special characters ko URL-friendly banata hai).	<code>{{ post.title urlencode }}</code>
Float Format <code>floatformat</code>	Decimal point ke baad kitne digits show karne hain, usey control karta hai. (e.g., 2 decimal places).	<code>{{ 1234.5678 floatformat:2 }}</code>
